```

## Metatype

Generated metatype information.

```
public IMetatype Metatype { get; }
```

**IMetatype** 

### MixinState

Arbitrary data that is shared between mixins. Mixins are free to store additional instance state in this blackboard.
<pre>public MixinBlackboard MixinState { get; }</pre>
MixinBlackboard
Recipes
<pre>public IImmutableList<irecipe> Recipes { get; }</irecipe></pre>
<u>IlmmutableList</u>
ServiceProvider
<pre>public IServiceProvider ServiceProvider { get; }</pre>
<u>IServiceProvider</u>
HasGodotClassMethod(in godot_string_name)
Check if the type contains a method with the given name. This method is used by Godot to check if a method exists before invoking it. Do not call or override this method.
<pre>protected override bool HasGodotClassMethod(in godot_string_name method)</pre>

### RestoreGodotObjectData(GodotSerializationInfo)

Restores this instance's state after reloading assemblies. Do not call or override this method. To add data to be saved and restored, implement Godot. IS erialization Listener.

protected override void RestoreGodotObjectData(GodotSerializationInfo info)

 $\prod$ 

info GodotSerializationInfo

Object that contains the previously saved data.

### SaveGodotObjectData(GodotSerializationInfo)

Saves this instance's state to be restored when reloading assemblies. Do not call or override this method. To add data to be saved and restored, implement Godot. IS erialization Listener.

protected override void SaveGodotObjectData(GodotSerializationInfo info)

info GodotSerializationInfo

Object used to save the data.

## Value()

Value that is provided by the provider.

public IServiceProvider Value()

## Notification(int)

Called when the object receives a notification, which can be identified in what by comparing it with a constant. See also Notification(int, bool).

```
public override void _Notification(int what)
{
    if (what == NotificationPredelete)
    {
        GD.Print("Goodbye!");
    }
}
```

**Note:** The base Godot.GodotObject defines a few notifications (Godot.GodotObject. NotificationPostinitialize and Godot.GodotObject.NotificationPredelete). Inheriting classes such as Godot.Node define a lot more notifications, which are also received by this method.

public override void \_Notification(int what)

what <u>int</u>♂

# Game.MetatypeMetadata []

```
ProjectStack
ProjectStack.dll

public class Game.MetatypeMetadata

Dispect ← Game.MetatypeMetadata

Attributes

Attributes

Attributes applied to the type itself.

public IReadOnlyDictionary<Type, Attribute[]> Attributes { get; }
```

### HasInitProperties

True if the type has init-only properties that must be set at construction. If this is true for a concrete type, you may call <a href="Months:Construct(IReadOnlyDictionary<string.object">Construct(IReadOnlyDictionary<string.object</a>). with a map of argument names to values to set these properties at construction.

```
public bool HasInitProperties { get; }

# InvokeGodotClassMethod(in godot\_string\_name, Native VariantPtrArgs, out godot variant)

 $\prod$ 

bool♂

method godot string name

Name of the method to check for.

Invokes the method with the given name, using the given arguments. This method is used by Godot to invoke methods from the engine side. Do not call or override this method.

<pre>protected override bool InvokeGodotClassMethod(in godot_string_name method, NativeVariantPtrArgs args, out godot_variant ret)</pre>
method godot_string_name
Name of the method to invoke.
args NativeVariantPtrArgs
Arguments to use with the invoked method.
ret godot_variant
Value returned by the invoked method.
<u>bool</u> ♂
RestoreGodotObjectData(GodotSerializationInfo)

Restores this instance's state after reloading assemblies. Do not call or override this method. To add data to be saved and restored, implement Godot. ISerialization Listener.

protected override void RestoreGodotObjectData(GodotSerializationInfo info)

info GodotSerializationInfo

Object that contains the previously saved data.

## SaveGodotObjectData(GodotSerializationInfo)

Saves this instance's state to be restored when reloading assemblies. Do not call or override this method. To add data to be saved and restored, implement Godot. IS erialization Listener.

protected override void SaveGodotObjectData(GodotSerializationInfo info)

info GodotSerializationInfo

Object used to save the data.

## \_Ready()

Called when the node is "ready", i.e. when both the node and its children have entered the scene tree. If the node has children, their Godot.Node.\_Ready() callbacks get triggered first, and the parent node will receive the ready notification afterwards.

Corresponds to the Godot.Node.NotificationReady notification in <u>Notification(int)</u>. See also the <code>@onready</code> annotation for variables.

Usually used for initialization. For even earlier initialization, Godot.GodotObject.Godot Object() may be used. See also Godot.Node. EnterTree().

**Note:** This method may be called only once for each node. After removing a node from the scene tree and adding it again, Godot.Node.\_Ready() will **not** be called a second time. This can be bypassed by requesting another call with Godot.Node.RequestReady(), which may be called anywhere before adding the node again.

public override void \_Ready()

#### Card.PropertyName

Cached StringNames for the properties and fields contained in this class, for fast lookup.

#### Card.SignalName

Cached StringNames for the signals contained in this class, for fast lookup.

#### Card.TaskNotifier

A wrapping class that can hold a <u>Task</u> value.

#### Card.TaskNotifier<T>

A wrapping class that can hold a <u>Task<TResult></u> ✓ value.

#### InfoTab

Base class for all UI-related nodes. Godot.Control features a bounding rectangle that defines its extents, an anchor position relative to its parent control or the current viewport, and offsets relative to the anchor. The offsets update automatically when the node, any of its parents, or the screen size change.

For more information on Godot's UI system, anchors, offsets, and containers, see the related tutorials in the manual. To build flexible UIs, you'll need a mix of UI elements that inherit from Godot.Control and Godot.Container nodes.

#### **User Interface nodes and input**

Godot propagates input events via viewports. Each Godot.Viewport is responsible for propagating Godot.InputEvents to their child nodes. As the Godot.SceneTree.Root is a Godot.Window, this already happens automatically for all UI elements in your game.

Input events are propagated through the Godot.SceneTree from the root node to all child nodes by calling Godot.Node. Input(Godot.InputEvent). For UI elements specifically, it

makes more sense to override the virtual method Godot.Control.\_Guilnput(Godot.Input Event), which filters out unrelated input events, such as by checking z-order, Godot. Control.MouseFilter, focus, or if the event was inside of the control's bounding box.

Call Godot.Control.AcceptEvent() so no other node receives the event. Once you accept an input, it becomes handled so Godot.Node.\_UnhandledInput(Godot.InputEvent) will not process it.

Only one Godot.Control node can be in focus. Only the node in focus will receive events. To get the focus, call Godot.Control.GrabFocus(). Godot.Control nodes lose focus when another node grabs it, or if you hide the node in focus.

Sets Godot.Control.MouseFilter to Godot.Control.MouseFilterEnum.Ignore to tell a Godot. Control node to ignore mouse or touch events. You'll need it if you place an icon on top of a button.

Godot.Theme resources change the Control's appearance. If you change the Godot. Theme on a Godot.Control node, it affects all of its children. To override some of the theme's parameters, call one of the add\_theme\_\*\_override methods, like Godot.Control. AddThemeFontOverride(Godot.StringName, Godot.Font). You can override the theme with the Inspector.

**Note:** Theme items are *not*Godot.GodotObject properties. This means you can't access their values using Godot.GodotObject.Get(Godot.StringName) and Godot.GodotObject. Set(Godot.StringName, Godot.Variant). Instead, use the get\_theme\_\* and add\_theme\_\*\_override methods provided by this class.

Set the value of a property contained in this class. This method is used by Godot to assign property values. Do not call or override this method.

<pre>protected override bool SetGodotClassPropertyValue(in godot_string_name name, in godot_variant value)</pre>
name godot_string_name
Name of the property to set.
value godot_variant
Value to set the property to if it was found.
<u>bool</u> ☑
true if a property with the given name was found.

# SetPropertyAndNotifyOnCompletion(ref TaskNotifier?, Task?, Action<Task?>, string?)

Compares the current and new values for a given field (which should be the backing field for a property). If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the field and then raises the <a href="PropertyChanged">PropertyChanged</a> event. This method is just like <a href="SetPropertyAnd">SetPropertyAnd</a> <a href="NotifyOnCompletion(ref TaskNotifier?">NotifyOnCompletion(ref TaskNotifier?</a>, <a href="Task?">Task?</a>, <a href="string?">string?</a>)</a>, with the difference being an extra <a href="Action<T>©</a> parameter with a callback being invoked either immediately, if the new task has already completed or is <a href="mailto:null@">null@</a>, or upon completion.

```
protected bool SetPropertyAndNotifyOnCompletion(ref Card.TaskNotifier? taskNotifier,
Task? newValue, Action<Task?> callback, string? propertyName = null)
```

#### taskNotifier <a href="Card">Card</a>.<a href="TaskNotifier">TaskNotifier</a>

The field notifier to modify.

#### newValue Task♂

The property's value after the change occurred.

#### callback Action Callback

A callback to invoke to update the property value.

#### propertyName <u>string</u> ☐

(optional) The name of the property that changed.

#### bool **♂**

<u>true</u> if the property was changed, <u>false</u> otherwise.

The <u>PropertyChanging</u> and <u>PropertyChanged</u> events are not raised if the current and new value for the target property are the same.

# SetPropertyAndNotifyOnCompletion(ref TaskNotifier?, Task?, string?)

Compares the current and new values for a given field (which should be the backing field for a property). If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the field and then raises the <a href="PropertyChanged">PropertyChanged</a> event. The behavior mirrors that of <a href="SetProperty<">SetProperty</a> (ref T, T, string?), with the difference being that this method will also monitor the new value of the property (a generic Task©) and will also raise the <a href="Property">Property</a> Changed again for the target property when it completes. This can be used to update bindings observing that <a href="Task©">Task©</a> or any of its properties. This method and its overload specifically rely on the <a href="Card.TaskNotifier">Card.TaskNotifier</a> type, which needs to be used in the backing field for the target <a href="Task©">Task©</a> property. The field doesn't need to be initialized, as this method will take care of doing that automatically. The <a href="Card.TaskNotifier">Card.TaskNotifier</a> type also includes an implicit operator, so it can be assigned to any <a href="Task©">Task©</a> instance directly. Here is a sample property declaration using this method:

```
private TaskNotifier myTask;
 public Task MyTask
  {
      get => myTask;
      private set => SetAndNotifyOnCompletion(ref myTask, value);
 }
 protected bool SetPropertyAndNotifyOnCompletion(ref Card.TaskNotifier? taskNotifier,
 Task? newValue, string? propertyName = null)
taskNotifier Card.TaskNotifier
  The field notifier to modify.
newValue <u>Task</u>♂
  The property's value after the change occurred.
propertyName <u>string</u>♂
  (optional) The name of the property that changed.
\Box\Box
bool♂
  <u>true</u> if the property was changed, <u>false</u> otherwise.
```

The <u>PropertyChanging</u> and <u>PropertyChanged</u> events are not raised if the current and new value for the target property are the same. The return value being true only indicates that the new value being assigned to taskNotifier is different than the previous one, and it does not mean the new <u>Task</u> instance passed as argument is in any particular state.

SetPropertyAndNotifyOnCompletion<T>(ref TaskNotifier<T>?, Task<T>?, Action<Task<T>?>, string?)

Compares the current and new values for a given field (which should be the backing field for a property). If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the field and then raises the <a href="PropertyChanged">PropertyChanged</a> event. This method is just like <a href="SetPropertyAndNotifyOnCompletion<T>(ref TaskNotifier<T>?, Task<T>?, string?)</a>, with the difference being an extra <a href="Action<T>@" parameter with a callback being invoked either immediately, if the new task has already completed or is null@", or upon completion.

protected bool SetPropertyAndNotifyOnCompletion<T>(ref Card.TaskNotifier<T>? taskNotifier, Task<T>? newValue, Action<Task<T>?> callback, string? propertyName = null)taskNotifier Card.TaskNotifier<T> The field notifier to modify. newValue <u>Task</u>♂<T> The property's value after the change occurred. callback Action callback Action A callback to invoke to update the property value. propertyName <u>string</u>♂ (optional) The name of the property that changed. bool ₫ <u>true</u> if the property was changed, <u>false</u> otherwise. Τ

The type of result for the <u>Task<TResult></u> do set and monitor.

The <u>PropertyChanging</u> and <u>PropertyChanged</u> events are not raised if the current and new value for the target property are the same.

# SetPropertyAndNotifyOnCompletion<T>(ref TaskNotifier<T>?, Task<T>?, string?)

Compares the current and new values for a given field (which should be the backing field for a property). If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the field and then raises the <a href="PropertyChanged">PropertyChanged</a> event. The behavior mirrors that of <a href="SetProperty<">SetProperty</a> (ref T, T, string?), with the difference being that this method will also monitor the new value of the property (a generic <a href="Task@">Task@"</a>) and will also raise the <a href="Property">Property</a> Changed again for the target property when it completes. This can be used to update bindings observing that <a href="Task@">Task@"</a> or any of its properties. This method and its overload specifically rely on the <a href="Card.TaskNotifier<T>">Card.TaskNotifier<T></a> type, which needs to be used in the backing field for the target <a href="Task@">Task@"</a> property. The field doesn't need to be initialized, as this method will take care of doing that automatically. The <a href="Card.TaskNotifier<T>">Card.TaskNotifier<T></a> type also includes an implicit operator, so it can be assigned to any <a href="Task@">Task@"</a> instance directly. Here is a sample property declaration using this method:

```
private TaskNotifier<int> myTask;

public Task<int> MyTask
{
    get => myTask;
    private set => SetAndNotifyOnCompletion(ref myTask, value);
}

protected bool SetPropertyAndNotifyOnCompletion<T>(ref Card.TaskNotifier<T>?
    taskNotifier, Task<T>? newValue, string? propertyName = null)

taskNotifier Card.TaskNotifier<T>
The field notifier to modify.

newValue Task
```

The property's value after the change occurred.

# propertyName string (optional) The name of the property that changed. ☐☐ bool true if the property was changed, false otherwise. ☐☐

Т

The type of result for the <u>Task<TResult></u> do set and monitor.

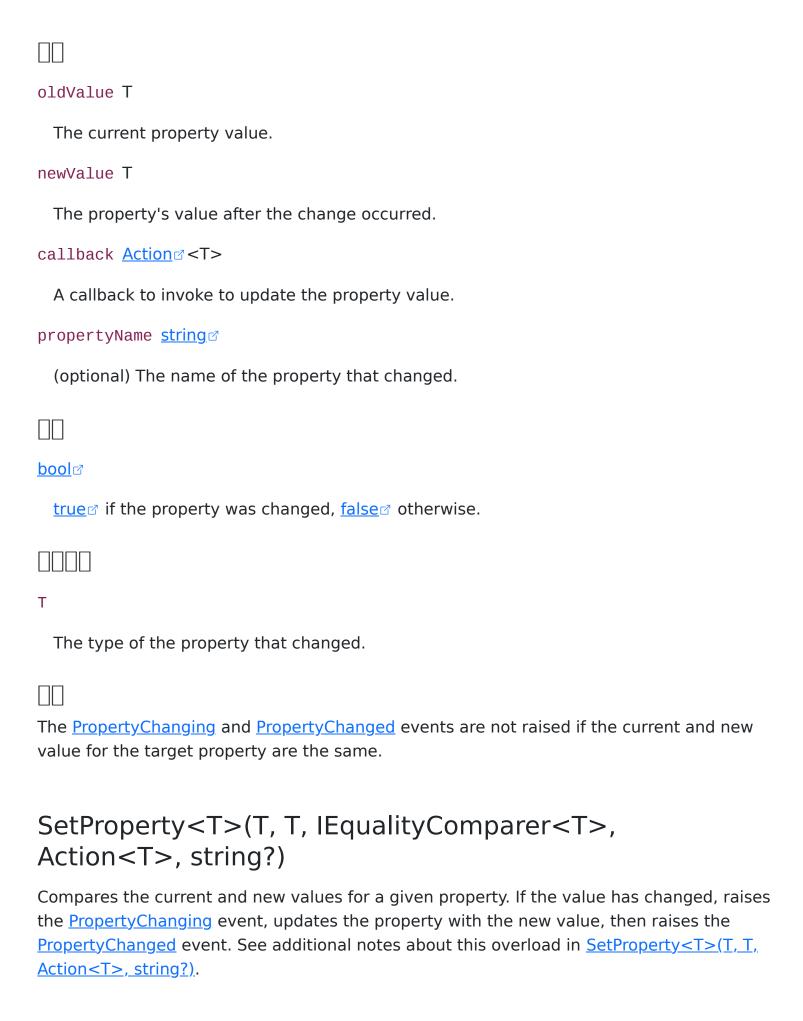

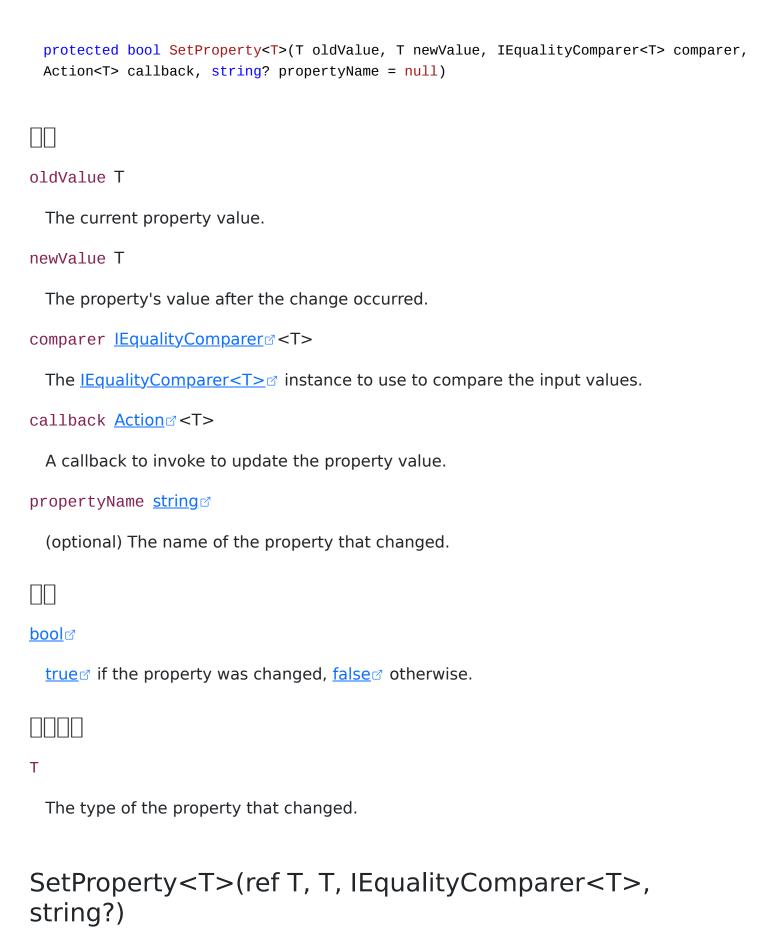

The <u>PropertyChanging</u> and <u>PropertyChanged</u> events are not raised if the current and new value for the target property are the same. The return value being <u>true</u> only indicates that the new value being assigned to <u>taskNotifier</u> is different than the previous one, and it does not mean the new <u>Task<TResult></u> instance passed as argument is in any particular state.

# SetProperty<T>(T, T, Action<T>, string?)

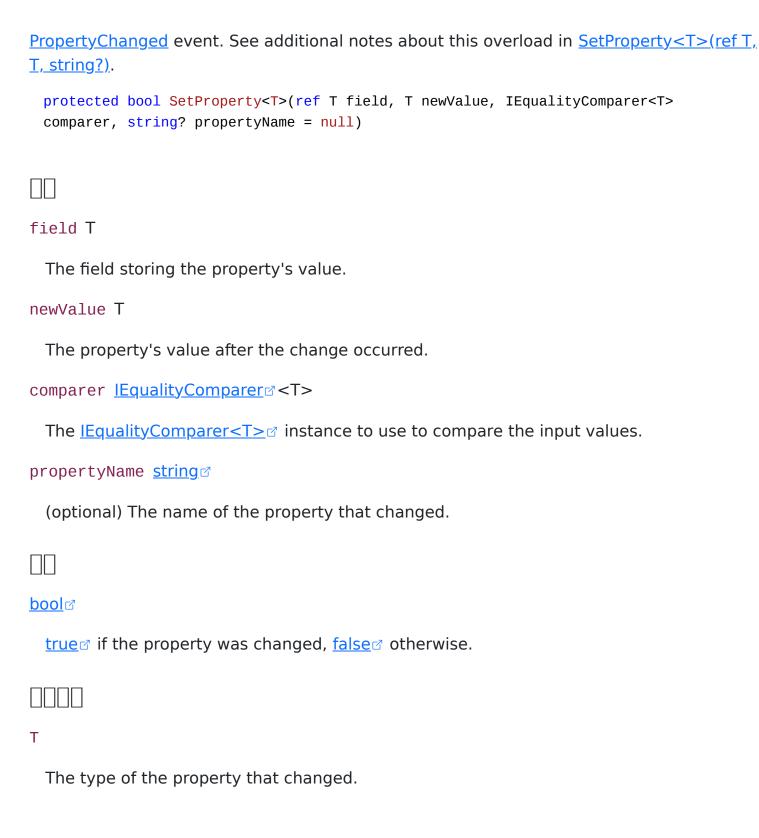

Compares the current and new values for a given property. If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the property with the new value, then raises the <a href="PropertyChanged">PropertyChanged</a> event. This overload is much less efficient than <a href="SetProperty<T>(ref T, T, string?">SetProperty<T>(ref T, T, string?)</a> and it should only be used when the former is not viable (eg. when the target property being updated does not directly expose a backing field that can be passed by reference). For performance reasons, it is recommended to use a stateful callback if possible through the <a href="SetProperty<TModel">SetProperty<TModel</a>, <a href="TotAT, T, TModel">TotAT, T, TModel</a>, <a href="Action<TModel">Action<TModel</a>, <a href="TotAT, T>">TNODEL</a>, <a href="TotAT, T>">TNODEL</a>, <a href="TotAT, T>">TMODEL</a>, <a href="TotAT, T>">TOTATE</a>, <a href="TotAT, T>">TOTATE</a>,

```
protected bool SetProperty<T>(T oldValue, T newValue, Action<T> callback, string?
propertyName = null)
```

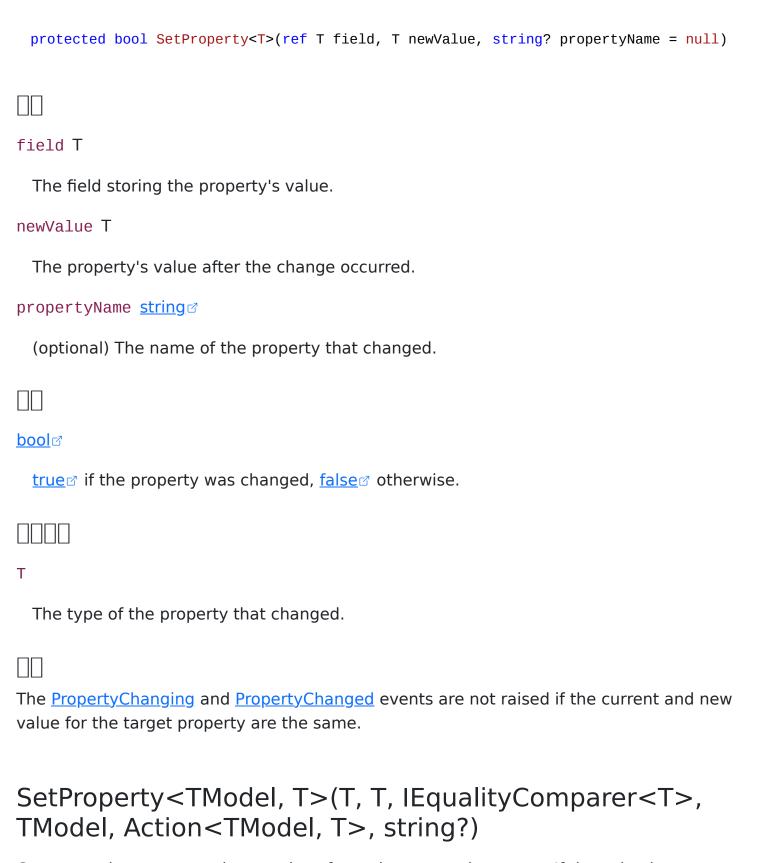

Compares the current and new values for a given property. If the value has changed, raises the <a href="https://example.com/Property/Changing">Property/Changing</a> event, updates the property with the new value, then raises the

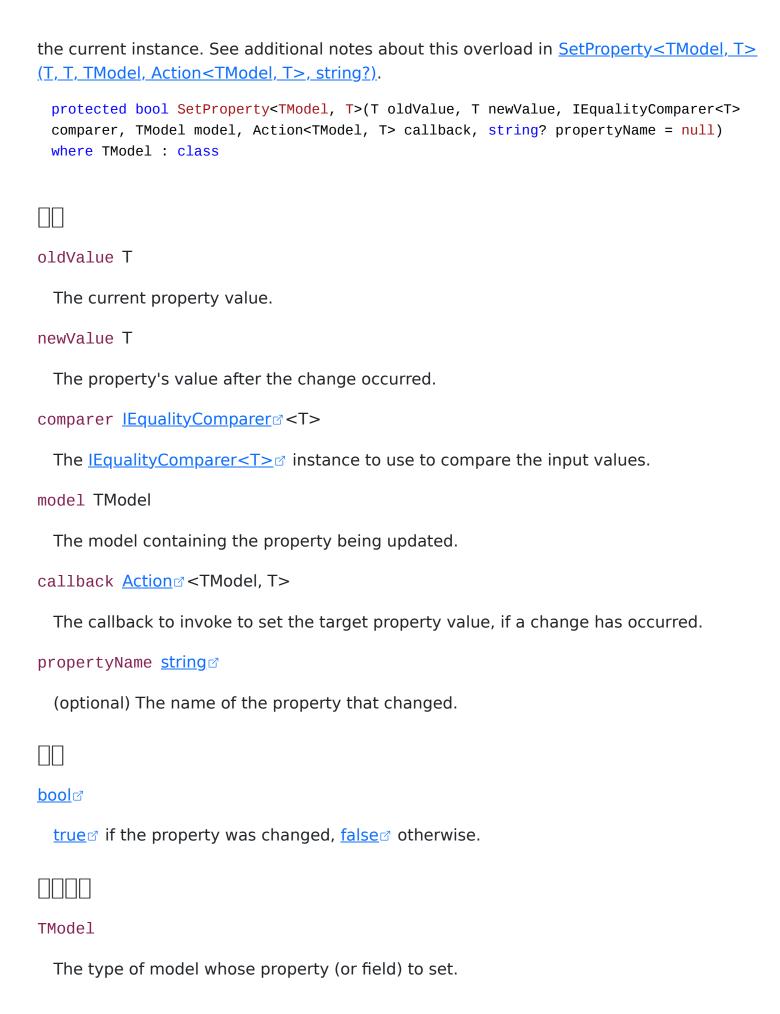

# SetProperty<T>(ref T, T, string?)

Compares the current and new values for a given property. If the value has changed, raises the <a href="https://example.com/PropertyChanging">PropertyChanging</a> event, updates the property with the new value, then raises the <a href="https://example.com/PropertyChanged">PropertyChanged</a> event.

Compares the current and new values for a given nested property. If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the property and then raises the <a href="PropertyChanged">PropertyChanged</a> event. The behavior mirrors that of <a href="SetProperty<T>(ref T, T, string?)</a>, with the difference being that this method is used to relay properties from a wrapped model in

The type of property (or field) to set.

# SetProperty<TModel, T>(T, T, TModel, Action<TModel, T>, string?)

Compares the current and new values for a given nested property. If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the property and then raises the <a href="PropertyChanged">PropertyChanged</a> event. The behavior mirrors that of <a href="SetProperty<T>(ref T, T, string?)</a>, with the difference being that this method is used to relay properties from a wrapped model in the current instance. This type is useful when creating wrapping, bindable objects that operate over models that lack support for notification (eg. for CRUD operations). Suppose we have this model (eg. for a database row in a table):

```
public class Person
{
    public string Name { get; set; }
}
```

We can then use a property to wrap instances of this type into our observable model (which supports notifications), injecting the notification to the properties of that model, like so:

```
[ObservableObject]
public class BindablePerson
{
    public Model { get; }

    public BindablePerson(Person model)
    {
        Model = model;
    }

    public string Name
    {
        get => Model.Name;
        set => Set(Model.Name, value, Model, (model, name) => model.Name = name);
    }
}
```

This way we can then use the wrapping object in our application, and all those "proxy" properties will also raise notifications when changed. Note that this method is not meant to be a replacement for <a href="SetProperty<T>(ref T, T, string?">SetProperty<T>(ref T, T, string?</a>), and it should only be used when relaying properties to a model that doesn't support notifications, and only if you can't implement notifications to that model directly (eg. by having it inherit from ObservableObject). The syntax relies on passing the target model and a stateless callback to allow the C# compiler to cache the function, which results in much better performance and no memory usage.

protected bool SetProperty<TModel, T>(T oldValue, T newValue, TModel model, Action<TModel, T> callback, string? propertyName = null) where TModel : class  $\Box\Box$ oldValue T The current property value. newValue T The property's value after the change occurred. model TModel The model containing the property being updated. callback Action < < TModel, T> The callback to invoke to set the target property value, if a change has occurred. (optional) The name of the property that changed. bool ₫ <u>true</u> if the property was changed, <u>false</u> otherwise.

**TModel** 

The type of model whose property (or field) to set.

Т

The type of property (or field) to set.

The <u>PropertyChanging</u> and <u>PropertyChanged</u> events are not raised if the current and new value for the target property are the same.

# UpdateAllZIndex()

```
public void UpdateAllZIndex()
```

# UpdateRecipe()

```
public void UpdateRecipe()
```

# UpdateZIndex()

```
public void UpdateZIndex()
```

## Notification(int)

Called when the object receives a notification, which can be identified in what by comparing it with a constant. See also <a href="Notification(int, bool)">Notification(int, bool)</a>.

```
public override void _Notification(int what)
{
    if (what == NotificationPredelete)
    {
        GD.Print("Goodbye!");
    }
}
```

**Note:** The base Godot.GodotObject defines a few notifications (Godot.GodotObject. NotificationPostinitialize and Godot.GodotObject.NotificationPredelete). Inheriting classes such as Godot.Node define a lot more notifications, which are also received by this method.

public override void \_Notification(int what)

what <u>int</u>♂

# \_Process(double)

Called during the processing step of the main loop. Processing happens at every frame and as fast as possible, so the delta time since the previous frame is not constant. delta is in seconds.

It is only called if processing is enabled, which is done automatically if this method is overridden, and can be toggled with <a href="SetProcess(bool)">SetProcess(bool)</a>.

Corresponds to the Godot.Node.NotificationProcess notification in <u>Notification(int)</u>.

**Note:** This method is only called if the node is present in the scene tree (i.e. if it's not an orphan).

public override void \_Process(double delta)

delta doubled

## Ready()

Called when the node is "ready", i.e. when both the node and its children have entered the scene tree. If the node has children, their Godot.Node.\_Ready() callbacks get triggered first, and the parent node will receive the ready notification afterwards.

Corresponds to the Godot.Node.NotificationReady notification in <u>Notification(int)</u>. See also the <code>@onready</code> annotation for variables.

Usually used for initialization. For even earlier initialization, Godot.GodotObject.Godot Object() may be used. See also Godot.Node. EnterTree().

**Note:** This method may be called only once for each node. After removing a node from the scene tree and adding it again, Godot.Node.\_Ready() will **not** be called a second time. This can be bypassed by requesting another call with Godot.Node.RequestReady(), which may be called anywhere before adding the node again.

public	override	void	_Ready()

public static readonly StringName ForceMotion

StringName

# InMoveing

Cached name for the 'InMoveing' field.

public static readonly StringName InMoveing

StringName

### **IsRoot**

Cached name for the 'IsRoot' property.

public static readonly StringName IsRoot

# 

StringName

# RootCard

Cached name for the 'RootCard' property. public static readonly StringName RootCard StringName **TargetPosition** Cached name for the 'TargetPosition' property. public static readonly StringName TargetPosition StringName **TextureRect** Cached name for the 'TextureRect' property. public static readonly StringName TextureRect StringName **TopCard** Cached name for the 'TopCard' property. public static readonly StringName TopCard

# **UppestCard**

Cached name for the 'UppestCard' property.

public static readonly StringName UppestCard

StringName

## bottomCard

Cached name for the '\_bottomCard' field.

public static readonly StringName \_bottomCard

StringName

## cardNameLabel

Cached name for the '\_cardNameLabel' field.

public static readonly StringName \_cardNameLabel

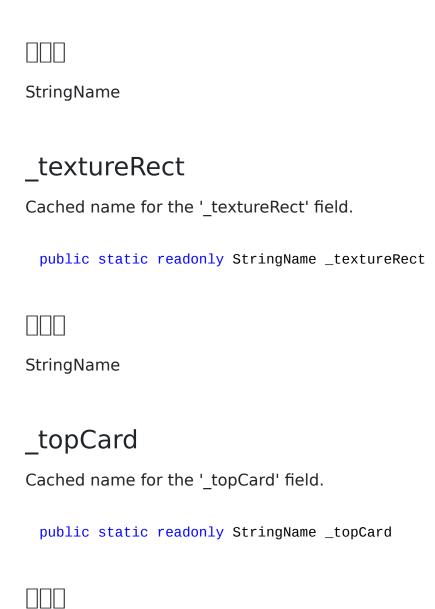

StringName

# \_characterBody

Cached name for the '\_characterBody' field.

<pre>public static readonly StringName _characterBody</pre>
StringName
game
Cached name for the '_game' field.
Cached hame for the _game held.
<pre>public static readonly StringName _game</pre>
StringName
_isExecutingRecipe
Cached name for the '_isExecutingRecipe' field.
<pre>public static readonly StringName _isExecutingRecipe</pre>
StringName
_isRoot
Cached name for the '_isRoot' field.
<pre>public static readonly StringName _isRoot</pre>
StringName

# \_isUppest Cached name for the '\_isUppest' field. public static readonly StringName \_isUppest StringName \_panel Cached name for the '\_panel' field. public static readonly StringName \_panel StringName \_ready2Group Cached name for the '\_ready2Group' field. public static readonly StringName \_ready2Group StringName \_targetPosition Cached name for the '\_targetPosition' field. public static readonly StringName \_targetPosition

StringName

# Card.SignalName []

# Card.TaskNotifier []

# Card.TaskNotifier<T> []

# InfoTab □

projectStack.Component

□□□: ProjectStack.dll

Base class for all UI-related nodes. Godot.Control features a bounding rectangle that defines its extents, an anchor position relative to its parent control or the current viewport, and offsets relative to the anchor. The offsets update automatically when the node, any of its parents, or the screen size change.

For more information on Godot's UI system, anchors, offsets, and containers, see the related tutorials in the manual. To build flexible UIs, you'll need a mix of UI elements that inherit from Godot.Control and Godot.Container nodes.

#### **User Interface nodes and input**

Godot propagates input events via viewports. Each Godot.Viewport is responsible for propagating Godot.InputEvents to their child nodes. As the Godot.SceneTree.Root is a Godot.Window, this already happens automatically for all UI elements in your game.

Input events are propagated through the Godot.SceneTree from the root node to all child nodes by calling Godot.Node.\_Input(Godot.InputEvent). For UI elements specifically, it makes more sense to override the virtual method Godot.Control.\_GuiInput(Godot.Input Event), which filters out unrelated input events, such as by checking z-order, Godot.Control. MouseFilter, focus, or if the event was inside of the control's bounding box.

Call Godot.Control.AcceptEvent() so no other node receives the event. Once you accept an input, it becomes handled so Godot.Node.\_UnhandledInput(Godot.InputEvent) will not process it.

Only one Godot.Control node can be in focus. Only the node in focus will receive events. To get the focus, call Godot.Control.GrabFocus(). Godot.Control nodes lose focus when another node grabs it, or if you hide the node in focus.

Sets Godot.Control.MouseFilter to Godot.Control.MouseFilterEnum.Ignore to tell a Godot. Control node to ignore mouse or touch events. You'll need it if you place an icon on top of a button.

Godot.Theme resources change the Control's appearance. If you change the Godot.Theme on a Godot.Control node, it affects all of its children. To override some of the theme's parameters, call one of the add\_theme\_\*\_override methods, like Godot.Control.AddTheme

FontOverride(Godot.StringName, Godot.Font). You can override the theme with the Inspector.

**Note:** Theme items are *not*Godot.GodotObject properties. This means you can't access their values using Godot.GodotObject.Get(Godot.StringName) and Godot.GodotObject. Set(Godot.StringName, Godot.Variant). Instead, use the get\_theme\_\* and add\_theme\_\*\_override methods provided by this class.

### Metatype

Generated metatype information.

```
public IMetatype Metatype { get; }
```

**IMetatype** 

#### **MixinState**

Arbitrary data that is shared between mixins. Mixins are free to store additional instance state in this blackboard.

```
public MixinBlackboard MixinState { get; }
```

MixinBlackboard

GetGodotClassPropertyValue(in godot_string_name, out godot_variant)
Get the value of a property contained in this class. This method is used by Godot to retrieve property values. Do not call or override this method.
<pre>protected override bool GetGodotClassPropertyValue(in godot_string_name name, out godot_variant value)</pre>
name godot_string_name
Name of the property to get.
value godot_variant
Value of the property if it was found.
<u>bool</u> ♂
true if a property with the given name was found.
HasGodotClassMethod(in godot_string_name)
Check if the type contains a method with the given name. This method is used by Godot to check if a method exists before invoking it. Do not call or override this method.
<pre>protected override bool HasGodotClassMethod(in godot_string_name method)</pre>
method godot_string_name
Name of the method to check for.

# InvokeGodotClassMethod(in godot\_string\_name, Native VariantPtrArgs, out godot variant)

Invokes the method with the given name, using the given arguments. This method is used by Godot to invoke methods from the engine side. Do not call or override this method.

protected override bool InvokeGodotClassMethod(in godot\_string\_name method, NativeVariantPtrArgs args, out godot\_variant ret)

method godot\_string\_name

Name of the method to invoke.

args NativeVariantPtrArgs

Arguments to use with the invoked method.

ret godot\_variant

Value returned by the invoked method.

# OnProcess(double)

Notification received from the tree every rendered frame when Godot.Node.lsPhysics Processing() returns true.

public void OnProcess(double delta)

delta <u>double</u>♂

Time since the last process update, in seconds.

# OnPropertyChanged(PropertyChangedEventArgs)

Raises the **PropertyChanged** event.

protected virtual void OnPropertyChanged(PropertyChangedEventArgs e)

e <u>PropertyChangedEventArgs</u>

☑

The input PropertyChangedEventArgs instance.

## OnPropertyChanged(string?)

Raises the **PropertyChanged** event.

protected void OnPropertyChanged(string? propertyName = null)

propertyName <u>string</u> ☐

(optional) The name of the property that changed.

## OnPropertyChanging(PropertyChangingEventArgs)

Raises the <u>PropertyChanging</u> event.

protected virtual void OnPropertyChanging(PropertyChangingEventArgs e)

e <u>PropertyChangingEventArgs</u>

☑

The input <u>PropertyChangingEventArgs</u> instance.

## OnPropertyChanging(string?)

Raises the **PropertyChanging** event.

protected void OnPropertyChanging(string? propertyName = null)

propertyName <u>string</u>♂

(optional) The name of the property that changed.

## OnReady()

Notification received when the node is ready.

public void OnReady()

# RestoreGodotObjectData(GodotSerializationInfo)

Restores this instance's state after reloading assemblies. Do not call or override this method. To add data to be saved and restored, implement Godot. IS erialization Listener.

protected override void RestoreGodotObjectData(GodotSerializationInfo info)

info GodotSerializationInfo

Object that contains the previously saved data.

# SaveGodotObjectData(GodotSerializationInfo)

Saves this instance's state to be restored when reloading assemblies. Do not call or override this method. To add data to be saved and restored, implement Godot. IS erialization Listener.

protected override void SaveGodotObjectData(GodotSerializationInfo info) info GodotSerializationInfo Object used to save the data. SetGodotClassPropertyValue(in godot string name, in godot variant) Set the value of a property contained in this class. This method is used by Godot to assign property values. Do not call or override this method. protected override bool SetGodotClassPropertyValue(in godot\_string\_name name, in godot\_variant value) name godot string name Name of the property to set. value godot variant Value to set the property to if it was found. bool ₫ <u>true</u> if a property with the given name was found.

# SetPropertyAndNotifyOnCompletion(ref TaskNotifier?, Task?, Action<Task?>, string?)

Compares the current and new values for a given field (which should be the backing field for a property). If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the field and then raises the <a href="PropertyChanged">PropertyChanged</a> event. This method is just like <a href="SetPropertyAnd">SetPropertyAnd</a> <a href="NotifyOnCompletion(ref TaskNotifier?">NotifyOnCompletion(ref TaskNotifier?</a>, <a href="Task?">Task?</a>, <a href="string?">string?</a>), with the difference being an extra <a href="Action<T>©">Action<T>©</a> parameter with a callback being invoked either immediately, if the new task has already completed or is <a href="mailto:null@">null@</a>, or upon completion.

protected bool SetPropertyAndNotifyOnCompletion(ref InfoTab.TaskNotifier? taskNotifier, Task? newValue, Action<Task?> callback, string? propertyName = null) taskNotifier InfoTab.TaskNotifier The field notifier to modify. newValue <u>Task</u>♂ The property's value after the change occurred. callback Action A callback to invoke to update the property value. propertyName <u>string</u>♂ (optional) The name of the property that changed. bool₫ <u>true</u> if the property was changed, <u>false</u> otherwise.  $\prod$ The <u>PropertyChanging</u> and <u>PropertyChanged</u> events are not raised if the current and new value for the target property are the same.

# SetPropertyAndNotifyOnCompletion(ref TaskNotifier?, Task?, string?)

Compares the current and new values for a given field (which should be the backing field for a property). If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the field and then raises the <a href="PropertyChanged">PropertyChanged</a> event. The behavior mirrors that of <a href="SetProperty<">SetProperty</a> (ref T, T, string?), with the difference being that this method will also monitor the new value of the property (a generic Taske) and will also raise the <a href="PropertyChanged">Property</a> Changed again for the target property when it completes. This can be used to update bindings observing that <a href="Taske">Taske</a> or any of its properties. This method and its overload specifically rely on the <a href="InfoTab.TaskNotifier">InfoTab.TaskNotifier</a> type, which needs to be used in the backing field for the target <a href="Taske">Task</a> property. The field doesn't need to be initialized, as this method will take care of doing that automatically. The <a href="InfoTab.TaskNotifier">InfoTab.TaskNotifier</a> type also includes an implicit operator, so it can be assigned to any <a href="Task">Task</a> instance directly. Here is a sample property declaration using this method:

```
private TaskNotifier myTask;
 public Task MyTask
 {
     get => myTask;
     private set => SetAndNotifyOnCompletion(ref myTask, value);
 }
 protected bool SetPropertyAndNotifyOnCompletion(ref InfoTab.TaskNotifier?
 taskNotifier, Task? newValue, string? propertyName = null)
taskNotifier InfoTab.TaskNotifier
 The field notifier to modify.
newValue Task♂
 The property's value after the change occurred.
(optional) The name of the property that changed.
```

<u>bool</u> ♂
true do if the property was changed, false do otherwise.
The <u>PropertyChanging</u> and <u>PropertyChanged</u> events are not raised if the current and new value for the target property are the same. The return value being <u>true</u> only indicates that the new value being assigned to <u>taskNotifier</u> is different than the previous one, and it does not mean the new <u>Task</u> instance passed as argument is in any particular state.
SetPropertyAndNotifyOnCompletion <t>(ref TaskNotifier<t>?, Task<t>?, Action<task<t>?&gt;, string?)</task<t></t></t></t>
Compares the current and new values for a given field (which should be the backing field for a property). If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the field and then raises the <a href="PropertyChanged">PropertyChanged</a> event. This method is just like <a action<t="" href="SetPropertyAndNotifyOnCompletion&lt;T&gt;(ref TaskNotifier&lt;T&gt;?, Task&lt;T&gt;?, string?)&lt;/a&gt;, with the difference being an extra &lt;a href=">@"&gt;Action<t>@</t></a> parameter with a callback being invoked either immediately, if the new task has already completed or is <a href="null@">null@</a> , or upon completion.
<pre>protected bool SetPropertyAndNotifyOnCompletion<t>(ref InfoTab.TaskNotifier<t>? taskNotifier, Task<t>? newValue, Action<task<t>?&gt; callback, string? propertyName = null)</task<t></t></t></t></pre>
taskNotifier <u>InfoTab</u> . <u>TaskNotifier</u> <t></t>
The field notifier to modify.
newValue <u>Task</u> ♂ <t></t>
The property's value after the change occurred.
callback <u>Action</u> ♂< <u>Task</u> ♂ <t>&gt;</t>
A callback to invoke to update the property value.

propertyName string

(optional) The name of the property that changed.

□□

bool

true if the property was changed, false otherwise.

Т

The type of result for the  $\underline{\mathsf{Task} < \mathsf{TResult} >}_{\mathsf{II}}$  to set and monitor.

The <u>PropertyChanging</u> and <u>PropertyChanged</u> events are not raised if the current and new value for the target property are the same.

## SetPropertyAndNotifyOnCompletion<T>(ref TaskNotifier<T>?, Task<T>?, string?)

Compares the current and new values for a given field (which should be the backing field for a property). If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the field and then raises the <a href="PropertyChanged">PropertyChanged</a> event. The behavior mirrors that of <a href="SetProperty<">SetProperty</a> (ref T, T, string?), with the difference being that this method will also monitor the new value of the property (a generic <a href="Task@">Task@"</a>) and will also raise the <a href="Property">Property</a> <a href="Changed">Changed</a> again for the target property when it completes. This can be used to update bindings observing that <a href="Task@">Task@</a> or any of its properties. This method and its overload specifically rely on the <a href="InfoTab.TaskNotifier<T>">InfoTab.TaskNotifier<T></a> type, which needs to be used in the backing field for the target <a href="Task@">Task@</a> property. The field doesn't need to be initialized, as this method will take care of doing that automatically. The <a href="InfoTab.TaskNotifier<T>">InfoTab.TaskNotifier<T></a> type also includes an implicit operator, so it can be assigned to any <a href="Task@">Task@"</a> instance directly. Here is a sample property declaration using this method:

```
private TaskNotifier<int> myTask;
public Task<int> MyTask
{
```

```
get => myTask;
     private set => SetAndNotifyOnCompletion(ref myTask, value);
 }
 protected bool SetPropertyAndNotifyOnCompletion<T>(ref InfoTab.TaskNotifier<T>?
 taskNotifier, Task<T>? newValue, string? propertyName = null)
taskNotifier InfoTab.TaskNotifier<T>
  The field notifier to modify.
newValue Taskd<T>
  The property's value after the change occurred.
(optional) The name of the property that changed.
bool♂
  <u>true</u> if the property was changed, <u>false</u> otherwise.
Т
  The type of result for the <u>Task<TResult></u> do set and monitor.
The <u>PropertyChanging</u> and <u>PropertyChanged</u> events are not raised if the current and new
```

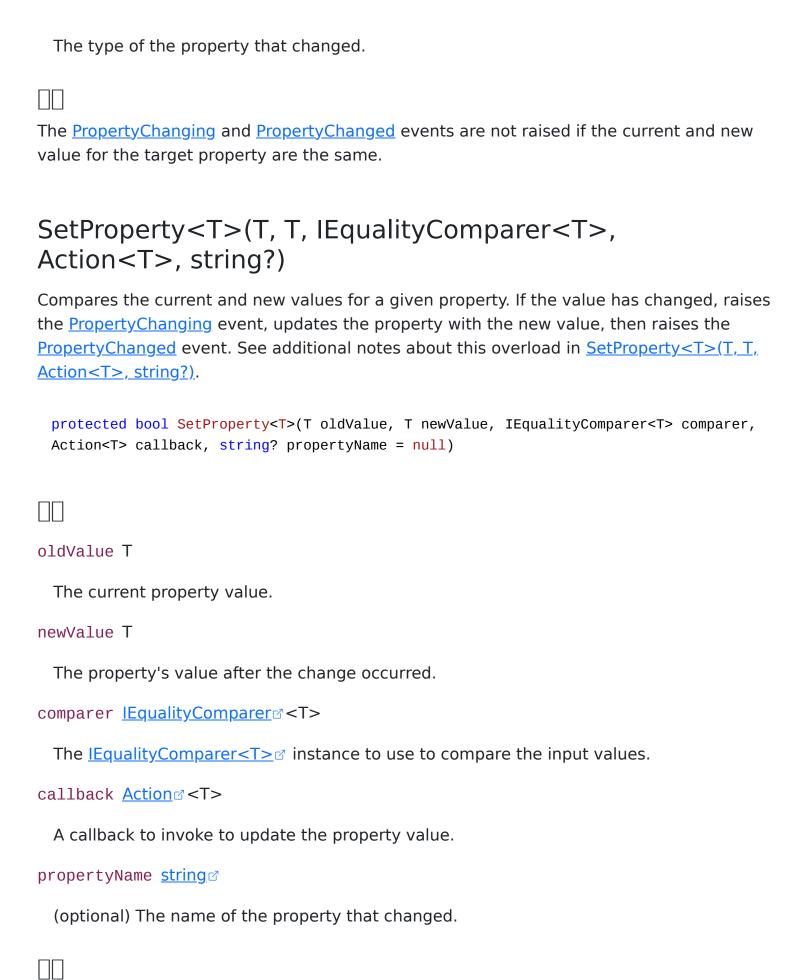

value for the target property are the same. The return value being true only indicates that the new value being assigned to taskNotifier is different than the previous one, and it does not mean the new <u>Task<TResult></u> instance passed as argument is in any particular state.

SetProperty<T>(T, T, Action<T>, string?)

Compares the current and new values for a given property. If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the property with the new value, then raises the <a href="PropertyChanged">PropertyChanged</a> event. This overload is much less efficient than <a href="SetProperty<T>(ref T, T, string?">SetProperty<T>(ref T, T, string?</a>) and it should only be used when the former is not viable (eg. when the target property being updated does not directly expose a backing field that can be passed by reference). For performance reasons, it is recommended to use a stateful callback if possible through the <a href="SetProperty<TModel">SetProperty<TModel</a>, <a href="TotAttons-TModel">TotAttons<TModel</a>, <a href="TotAttons-TModel">TotAttons<TModel</a>, <a href="TotAttons-TModel">TotAttons</a>, <a href="String?">String?</a>) whenever possible instead of this overload, as that will allow the C# compiler to cache the input callback and reduce the memory allocations. More info on that overload are available in the related XML docs. This overload is here for completeness and in cases where that is not applicable.

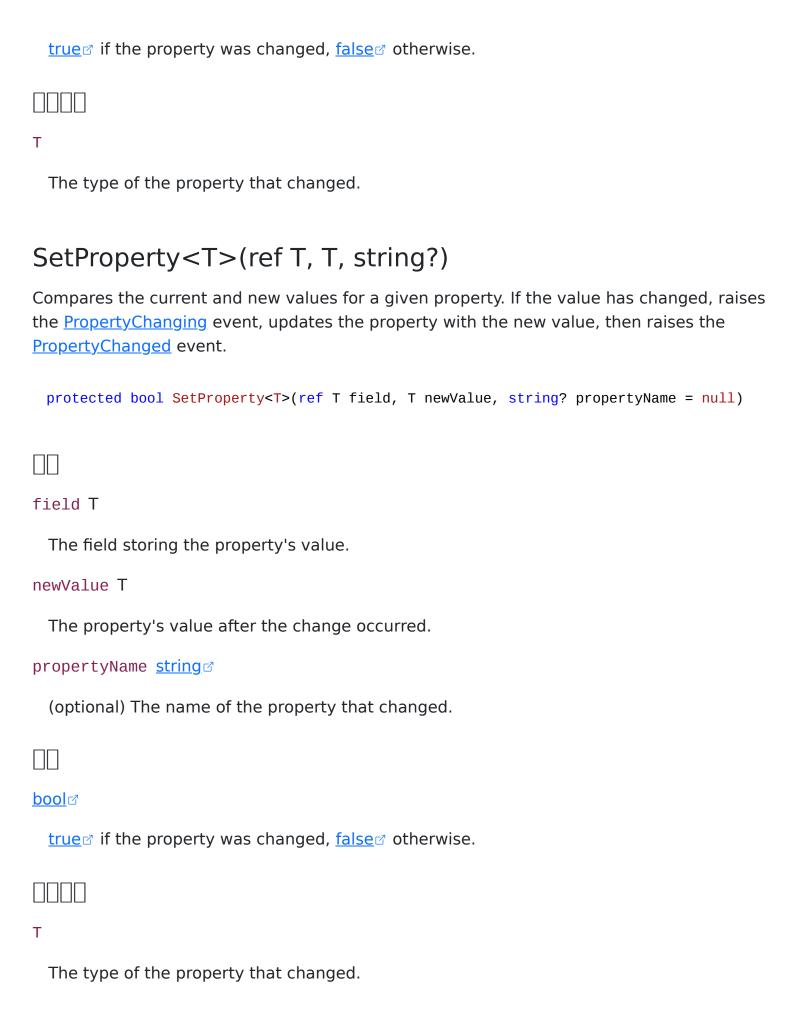

```
protected bool SetProperty<T>(T oldValue, T newValue, Action<T> callback, string?
 propertyName = null)
oldValue T
  The current property value.
newValue T
  The property's value after the change occurred.
callback <u>Action</u> < < T >
  A callback to invoke to update the property value.
propertyName string
  (optional) The name of the property that changed.
\Box\Box
bool ₫
  <u>true</u> if the property was changed, <u>false</u> otherwise.
```

Т

<u>bool</u> ♂
true do if the property was changed, false do otherwise.
т
The type of the property that changed.
SetProperty <t>(ref T, T, IEqualityComparer<t>, string?)</t></t>
Compares the current and new values for a given property. If the value has changed, raises the <a href="https://example.com/PropertyChanging">PropertyChanging</a> event, updates the property with the new value, then raises the <a href="https://example.com/PropertyChanged">PropertyChanged</a> event. See additional notes about this overload in <a example.com="" href="https://example.com/SetProperty&lt;/a&gt; (ref T, &lt;a href=" https:="" trystring?"="">T, string?</a> ).
<pre>protected bool SetProperty<t>(ref T field, T newValue, IEqualityComparer<t> comparer, string? propertyName = null)</t></t></pre>
field T
The field storing the property's value.
newValue T
The property's value after the change occurred.
comparer <u>IEqualityComparer</u> < T>
The <u>IEqualityComparer<t></t></u> instance to use to compare the input values.
propertyName <u>string</u> ♂
(optional) The name of the property that changed.

<u>bool</u>♂

The <u>PropertyChanging</u> and <u>PropertyChanged</u> events are not raised if the current and new value for the target property are the same.

## SetProperty<TModel, T>(T, T, IEqualityComparer<T>, TModel, Action<TModel, T>, string?)

Compares the current and new values for a given nested property. If the value has changed, raises the <a href="PropertyChanging">PropertyChanging</a> event, updates the property and then raises the <a href="PropertyChanged">PropertyChanged</a> event. The behavior mirrors that of <a href="SetProperty<T>(ref T, T, string?)</a>, with the difference being that this method is used to relay properties from a wrapped model in the current instance. See additional notes about this overload in <a href="SetProperty<TModel">SetProperty<TModel</a>, <a href="Total">T></a>, <a href="Total">String?</a>).

protected bool SetProperty<TModel, T>(T oldValue, T newValue, IEqualityComparer<T>
comparer, TModel model, Action<TModel, T> callback, string? propertyName = null)
where TModel : class

#### 

#### oldValue T

The current property value.

#### newValue T

The property's value after the change occurred.

comparer <u>IEqualityComparer</u> < T>

The <u>IEqualityComparer<T></u> instance to use to compare the input values.

#### model TModel

The model containing the property being updated.

callback Action < < TModel, T>

The callback to invoke to set the target property value, if a change has occurred.

propertyName string

(optional) The name of the property that changed.

<u>bool</u> ♂

<u>true</u> if the property was changed, <u>false</u> otherwise.

#### **TModel**

The type of model whose property (or field) to set.

Т

The type of property (or field) to set.

## SetProperty<TModel, T>(T, T, TModel, Action<TModel, T>, string?)

Compares the current and new values for a given nested property. If the value has changed, raises the <u>PropertyChanging</u> event, updates the property and then raises the <u>PropertyChanged</u> event. The behavior mirrors that of <u>SetProperty<T>(ref T, T, string?)</u>, with the difference being that this method is used to relay properties from a wrapped model in the current instance. This type is useful when creating wrapping, bindable objects that operate over models that lack support for notification (eg. for CRUD operations). Suppose we have this model (eg. for a database row in a table):

```
public class Person
{
    public string Name { get; set; }
}
```

We can then use a property to wrap instances of this type into our observable model (which supports notifications), injecting the notification to the properties of that model, like so:

```
[ObservableObject]
public class BindablePerson
{
   public Model { get; }
```

```
public BindablePerson(Person model)
{
    Model = model;
}

public string Name
{
    get => Model.Name;
    set => Set(Model.Name, value, Model, (model, name) => model.Name = name);
}
}
```

This way we can then use the wrapping object in our application, and all those "proxy" properties will also raise notifications when changed. Note that this method is not meant to be a replacement for <a href="SetProperty<T>(ref T, T, string?">SetProperty<T>(ref T, T, string?)</a>), and it should only be used when relaying properties to a model that doesn't support notifications, and only if you can't implement notifications to that model directly (eg. by having it inherit from ObservableObject). The syntax relies on passing the target model and a stateless callback to allow the C# compiler to cache the function, which results in much better performance and no memory usage.

```
protected bool SetProperty<TModel, T>(T oldValue, T newValue, TModel model,
Action<TModel, T> callback, string? propertyName = null) where TModel : class
```

#### oldValue T

The current property value.

#### newValue T

The property's value after the change occurred.

#### model TModel

The model containing the property being updated.

```
callback Action Callback Action
```

The callback to invoke to set the target property value, if a change has occurred.

```
propertyName <u>string</u>♂
```

(optional) The name of the property that changed.

bool₫

<u>true</u> if the property was changed, <u>false</u> otherwise.

#### **TModel**

The type of model whose property (or field) to set.

Т

The type of property (or field) to set.

The <u>PropertyChanging</u> and <u>PropertyChanged</u> events are not raised if the current and new value for the target property are the same.

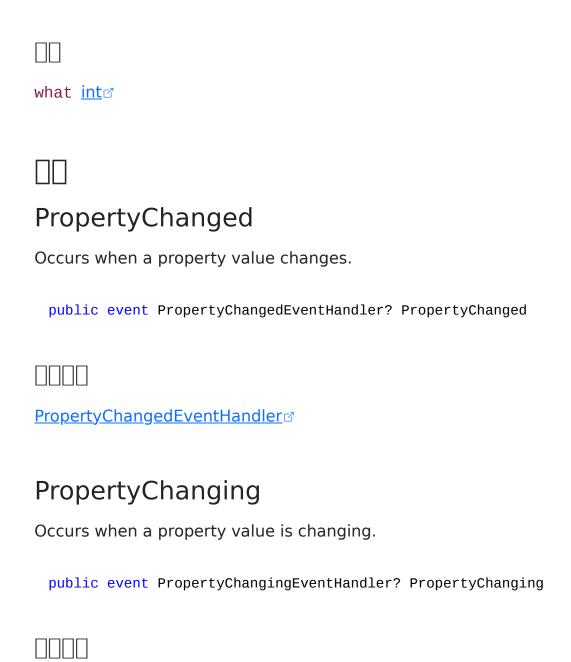

#### \_Notification(int)

Called when the object receives a notification, which can be identified in what by comparing it with a constant. See also Notification(int, bool).

```
public override void _Notification(int what)
{
    if (what == NotificationPredelete)
    {
        GD.Print("Goodbye!");
    }
}
```

**Note:** The base Godot.GodotObject defines a few notifications (Godot.GodotObject. NotificationPostinitialize and Godot.GodotObject.NotificationPredelete). Inheriting classes such as Godot.Node define a lot more notifications, which are also received by this method.

```
public override void _Notification(int what)
```

 $\underline{PropertyChangingEventHandler} \boxdot$ 

### InfoTab.MetatypeMetadata []

□□□□: ProjectStack.Component
□□□: ProjectStack.dll
<pre>public class InfoTab.MetatypeMetadata</pre>
<u>object</u> do ← InfoTab.MetatypeMetadata
Attributes
Attributes applied to the type itself.
